

# Chapter 7:

## Dislocations & Strengthening Mechanisms

### ISSUES TO ADDRESS...

- Why are dislocations observed primarily in metals and alloys?
- How are strength and dislocation motion related?
- How do we increase strength?
- How can heating change strength and other properties?

# Dislocations & Materials Classes

- Metals: Disl. motion easier.
  - non-directional bonding
  - close-packed directions for slip.

electron cloud

- Covalent Ceramics (Si, diamond): Motion hard.
  - directional (angular) bonding

- Ionic Ceramics (NaCl): Motion hard.
  - need to avoid ++ and -- neighbors.

# Dislocation Motion

## Dislocations & plastic deformation

- Cubic & hexagonal metals - plastic deformation by **plastic shear or slip** where one plane of atoms slides over adjacent plane by defect motion (dislocations).

- If dislocations don't move, deformation doesn't occur!

Adapted from Fig. 7.1,  
Callister 7e.

# Dislocation Motion

- Dislocation moves along **slip plane** in **slip direction** perpendicular to dislocation line
- Slip direction same direction as **Burgers vector**

**Edge dislocation**

Adapted from Fig. 7.2,  
*Callister 7e.*

**Screw dislocation**

# Deformation Mechanisms

## Slip System

- Slip plane - plane allowing easiest slippage
  - Wide interplanar spacings - highest planar densities
- Slip direction - direction of movement - Highest linear densities

Adapted from Fig. 7.6, Callister 7e.

- FCC Slip occurs on  $\{111\}$  planes (close-packed) in  $\langle 110 \rangle$  directions (close-packed)
  - => total of 12 slip systems in FCC
- in BCC & HCP other slip systems occur

# Stress and Dislocation Motion

- Crystals slip due to a **resolved shear stress**,  $\tau_R$ .
- Applied tension can produce such a stress.

Applied **tensile**  
stress:  $\sigma = F/A$

Resolved shear  
stress:  $\tau_R = F_S/A_S$

Relation between  
 $\sigma$  and  $\tau_R$

$$\tau_R = \sigma \cos \lambda \cos \phi$$

# Critical Resolved Shear Stress

- Condition for dislocation motion:
- Crystal orientation can make it easy or hard to move dislocation

$$\tau_R > \tau_{\text{CRSS}}$$

↑  
typically  
 $10^{-4}$  GPa to  $10^{-2}$  GPa

$$\tau_R = \sigma \cos \lambda \cos \phi$$

$\tau$  maximum at  $\lambda = \phi = 45^\circ$

# Single Crystal Slip

Adapted from Fig. 7.9, *Callister 7e*.

Adapted from Fig. 7.8, *Callister 7e*.

# Ex: Deformation of single crystal

- a) Will the single crystal yield?
- b) If not, what stress is needed?

$$\tau_{\text{crss}} = 3000 \text{ psi}$$

$$\tau = \sigma \cos \lambda \cos \phi$$

$$\sigma = 6500 \text{ psi}$$

$$\begin{aligned} \tau &= (6500 \text{ psi}) (\cos 35^\circ) (\cos 60^\circ) \\ &= (6500 \text{ psi}) (0.41) \end{aligned}$$

$$\tau = 2662 \text{ psi} < \tau_{\text{crss}} = 3000 \text{ psi}$$

So the applied stress of 6500 psi will not cause the crystal to yield.

# Ex: Deformation of single crystal

What stress *is* necessary (i.e., what is the yield stress,  $\sigma_y$ )?

$$\tau_{\text{crss}} = 3000 \text{ psi} = \sigma_y \cos \lambda \cos \phi = \sigma_y (0.41)$$

$$\therefore \sigma_y = \frac{\tau_{\text{crss}}}{\cos \lambda \cos \phi} = \frac{3000 \text{ psi}}{0.41} = \underline{\underline{7325 \text{ psi}}}$$

So for deformation to occur the applied stress must be greater than or equal to the yield stress

$$\sigma \geq \sigma_y = 7325 \text{ psi}$$

# Slip Motion in Polycrystals

- Stronger - grain boundaries pin deformations
- Slip planes & directions ( $\lambda$ ,  $\phi$ ) change from one crystal to another.
- $\tau_R$  will vary from one crystal to another.
- The crystal with the largest  $\tau_R$  yields first.
- Other (less favorably oriented) crystals yield later.

Adapted from Fig. 7.10, *Callister 7e*.  
(Fig. 7.10 is courtesy of C. Brady, National Bureau of Standards [now the National Institute of Standards and Technology, Gaithersburg, MD].)

# Anisotropy in $\sigma_y$

- Can be induced by rolling a polycrystalline metal

- before rolling

- isotropic

since grains are approx. spherical & randomly oriented.

- after rolling

rolling direction

- anisotropic

since rolling affects grain orientation and shape.

Adapted from Fig. 7.11, *Callister 7e*. (Fig. 7.11 is from W.G. Moffatt, G.W. Pearsall, and J. Wulff, *The Structure and Properties of Materials*, Vol. I, *Structure*, p. 140, John Wiley and Sons, New York, 1964.)

# Anisotropy in Deformation

1. Cylinder of Tantalum machined from a rolled plate:

2. Fire cylinder at a target.

3. Deformed cylinder

plate thickness direction

- The noncircular end view shows anisotropic deformation of rolled material.

# 4 Strategies for Strengthening:

## 1: Reduce Grain Size

- Grain boundaries are barriers to slip.
- Barrier "strength" increases with increasing angle of misorientation.
- Smaller grain size: more barriers to slip.

Adapted from Fig. 7.14, *Callister 7e*.  
(Fig. 7.14 is from *A Textbook of Materials Technology*, by Van Vlack, Pearson Education, Inc., Upper Saddle River, NJ.)

- Hall-Petch Equation:

$$\sigma_{yield} = \sigma_o + k_y d^{-1/2}$$

# 4 Strategies for Strengthening:

## 2: Solid Solutions

- Impurity atoms distort the lattice & generate stress.
- Stress can produce a barrier to dislocation motion.
- Smaller substitutional impurity

Impurity generates local stress at **A** and **B** that opposes dislocation motion to the right.

- Larger substitutional impurity

Impurity generates local stress at **C** and **D** that opposes dislocation motion to the right.

# Stress Concentration at Dislocations

Adapted from Fig. 7.4,  
*Callister 7e.*

# Strengthening by Alloying

- small impurities tend to concentrate at dislocations
- reduce mobility of dislocation  $\therefore$  increase strength

Adapted from Fig.  
7.17, *Callister 7e*.

# Strengthening by alloying

- large impurities concentrate at dislocations on low density side

(a)

Adapted from Fig.  
7.18, *Callister 7e*.

(b)

# Ex: Solid Solution Strengthening in Copper

- Tensile strength & yield strength increase with wt% Ni.

Adapted from Fig. 7.16 (a) and (b), Callister 7e.

- Empirical relation:  $\sigma_y \sim C^{1/2}$
- Alloying increases  $\sigma_y$  and *TS*.

# 4 Strategies for Strengthening:

## 3: Precipitation Strengthening

- Hard precipitates are difficult to shear.  
Ex: Ceramics in metals (SiC in Iron or Aluminum).

- Result:  $\sigma_y \sim \frac{1}{S}$

# Application: Precipitation Strengthening

- Internal wing structure on Boeing 767

Adapted from chapter-opening photograph, Chapter 11, *Callister 5e*. (courtesy of G.H. Narayanan and A.G. Miller, Boeing Commercial Airplane Company.)

- Aluminum is strengthened with precipitates formed by alloying.

Adapted from Fig. 11.26, *Callister 7e*. (Fig. 11.26 is courtesy of G.H. Narayanan and A.G. Miller, Boeing Commercial Airplane Company.)

# 4 Strategies for Strengthening:

## 4: Cold Work (%CW)

- Room temperature deformation.
- Common forming operations change the cross sectional area:

-Forging

Adapted from Fig. 11.8, Callister 7e.

-Rolling

-Drawing

-Extrusion

$$\%CW = \frac{A_o - A_d}{A_o} \times 100$$

# Dislocations During Cold Work

- Ti alloy after cold working:

- Dislocations entangle with one another during **cold work**.
- Dislocation motion becomes more difficult.

Adapted from Fig. 4.6, *Callister 7e*.  
(Fig. 4.6 is courtesy of M.R. Plichta, Michigan Technological University.)

# Result of Cold Work

$$\text{Dislocation density} = \frac{\text{total dislocation length}}{\text{unit volume}}$$

- Carefully grown single crystal  
→ ca.  $10^3 \text{ mm}^{-2}$
- Deforming sample increases density  
→  $10^9$ - $10^{10} \text{ mm}^{-2}$
- Heat treatment reduces density  
→  $10^5$ - $10^6 \text{ mm}^{-2}$

- Yield stress increases as  $\rho_d$  increases:

# Effects of Stress at Dislocations

Adapted from Fig.  
7.5, Callister 7e.

# Impact of Cold Work

As cold work is increased

- Yield strength ( $\sigma_y$ ) increases.
- Tensile strength ( $TS$ ) increases.
- Ductility ( $\%EL$  or  $\%AR$ ) decreases.

Adapted from Fig. 7.20, Callister 7e.

# Cold Work Analysis

- What is the tensile strength & ductility after cold working?

$$\%CW = \frac{\pi r_o^2 - \pi r_d^2}{\pi r_o^2} \times 100 = 35.6\%$$

Adapted from Fig. 7.19, Callister 7e. (Fig. 7.19 is adapted from *Metals Handbook: Properties and Selection: Iron and Steels*, Vol. 1, 9th ed., B. Bardes (Ed.), American Society for Metals, 1978, p. 226; and *Metals Handbook: Properties and Selection: Nonferrous Alloys and Pure Metals*, Vol. 2, 9th ed., H. Baker (Managing Ed.), American Society for Metals, 1979, p. 276 and 327.)

# $\sigma$ - $\epsilon$ Behavior vs. Temperature

- Results for polycrystalline iron:

Adapted from Fig. 6.14,  
Callister 7e.

- $\sigma_y$  and  $TS$  *decrease* with increasing test temperature.
- % $EL$  *increases* with increasing test temperature.
- Why? Vacancies help dislocations move past obstacles.

# Effect of Heating After %CW

- 1 hour treatment at  $T_{\text{anneal}}$ ...  
decreases  $TS$  and increases  $\%EL$ .
- Effects of cold work are reversed!

- 3 Annealing stages to discuss...

Adapted from Fig. 7.22, *Callister 7e*. (Fig. 7.22 is adapted from G. Sachs and K.R. van Horn, *Practical Metallurgy, Applied Metallurgy, and the Industrial Processing of Ferrous and Nonferrous Metals and Alloys*, American Society for Metals, 1940, p. 139.)

# Recovery

Annihilation reduces dislocation density.

- Scenario 1  
Results from diffusion

- Scenario 2

3. “Climbed” disl. can now move on new slip plane

2. grey atoms leave by vacancy diffusion allowing disl. to “climb”

1. dislocation blocked; can’t move to the right

# Recrystallization

- New grains are formed that:
  - have a small dislocation density
  - are small
  - consume cold-worked grains.

Adapted from  
Fig. 7.21 (a),(b),  
*Callister 7e*.  
(Fig. 7.21 (a),(b)  
are courtesy of  
J.E. Burke,  
General Electric  
Company.)

# Further Recrystallization

- All cold-worked grains are consumed.

Adapted from  
Fig. 7.21 (c),(d),  
*Callister 7e*.  
(Fig. 7.21 (c),(d)  
are courtesy of  
J.E. Burke,  
General Electric  
Company.)

# Grain Growth

- At longer times, larger grains consume smaller ones.
- Why? Grain boundary area (and therefore energy) is reduced.

Adapted from  
Fig. 7.21 (d),(e),  
*Callister 7e*.  
(Fig. 7.21 (d),(e)  
are courtesy of  
J.E. Burke,  
General Electric  
Company.)

- Empirical Relation:

exponent typ.  $\sim 2$   
grain diam.  
at time  $t$ .

$$d^n - d_o^n = Kt$$

coefficient dependent  
on material and  $T$ .

elapsed time

Ostwald Ripening

$T_R$  = recrystallization temperature

Adapted from Fig. 7.22, Callister 7e.

# Recrystallization Temperature, $T_R$

$T_R$  = recrystallization temperature = point of highest rate of property change

1.  $T_m \Rightarrow T_R \approx 0.3-0.6 T_m$  (K)
2. Due to diffusion  $\rightarrow$  annealing time  $\rightarrow T_R = f(t)$   
shorter annealing time  $\Rightarrow$  higher  $T_R$
3. Higher %CW  $\Rightarrow$  lower  $T_R$  – strain hardening
4. Pure metals lower  $T_R$  due to dislocation movements
  - Easier to move in pure metals  $\Rightarrow$  lower  $T_R$

# Coldwork Calculations

A cylindrical rod of brass originally 0.40 in (10.2 mm) in diameter is to be cold worked by drawing. The circular cross section will be maintained during deformation. A cold-worked tensile strength in excess of 55,000 psi (380 MPa) and a ductility of at least 15 %*EL* are desired. Further more, the final diameter must be 0.30 in (7.6 mm). Explain how this may be accomplished.

# Coldwork Calculations Solution

If we directly draw to the final diameter what happens?

$$\begin{aligned}\%CW &= \left( \frac{A_o - A_f}{A_o} \right) \times 100 = \left( 1 - \frac{A_f}{A_o} \right) \times 100 \\ &= \left( 1 - \frac{\pi D_f^2 / 4}{\pi D_o^2 / 4} \right) \times 100 = \left( 1 - \left( \frac{0.30}{0.40} \right)^2 \right) \times 100 = 43.8\%\end{aligned}$$

# Coldwork Calc Solution: Cont.

Adapted from Fig. 7.19, Callister 7e.

- For %CW = 43.8%
  - $\sigma_y = 420$  MPa
  - $TS = 540$  MPa > 380 MPa
  - %EL = 6 < 15
- This doesn't satisfy criteria..... what can we do?

# Coldwork Calc Solution: Cont.

Adapted from Fig. 7.19, Callister 7e.

For  $TS > 380 \text{ MPa}$   $\longrightarrow$   $> 12 \%CW$

For  $\%EL < 15$   $\longrightarrow$   $< 27 \%CW$

$\therefore$  our working range is limited to  $\%CW = 12-27$

# Coldwork Calc Soln: Recrystallization

Cold draw-anneal-cold draw again

- For objective we need a cold work of  $\%CW \cong 12-27$ 
  - We'll use  $\%CW = 20$
- Diameter after first cold draw (before 2<sup>nd</sup> cold draw)?
  - must be calculated as follows:

$$\%CW = \left(1 - \frac{D_{f2}^2}{D_{02}^2}\right) \times 100 \Rightarrow 1 - \frac{D_{f2}^2}{D_{02}^2} = \frac{\%CW}{100}$$

$$\frac{D_{f2}}{D_{02}} = \left(1 - \frac{\%CW}{100}\right)^{0.5} \Rightarrow D_{02} = \frac{D_{f2}}{\left(1 - \frac{\%CW}{100}\right)^{0.5}}$$

$$\text{Intermediate diameter} = D_{f1} = D_{02} = 0.30 / \left(1 - \frac{20}{100}\right)^{0.5} = \underline{\underline{0.335 \text{ m}}}$$

# Coldwork Calculations Solution

Summary:

1. Cold work  $D_{01} = 0.40 \text{ in} \rightarrow D_{f1} = 0.335 \text{ m}$

$$\%CW_1 = \left( 1 - \left( \frac{0.335}{0.4} \right)^2 \right) \times 100 = 30$$

2. Anneal above  $D_{02} = D_{f1}$

3. Cold work  $D_{02} = 0.335 \text{ in} \rightarrow D_{f2} = 0.30 \text{ m}$

$$\%CW_2 = \left( 1 - \left( \frac{0.3}{0.335} \right)^2 \right) \times 100 = 20 \quad \text{Fig 7.19} \Rightarrow$$

$$\sigma_y = 340 \text{ MPa}$$

$$TS = 400 \text{ MPa}$$

$$\%EL = 24$$

Therefore, meets all requirements

# Rate of Recrystallization

$$\log R = -\log t = \log R_0 - \frac{E}{kT}$$

$$\log t = C + \frac{B}{T}$$

note :  $R = 1/t$

- Hot work  $\rightarrow$  above  $T_R$
- Cold work  $\rightarrow$  below  $T_R$
- Smaller grains
  - stronger at low temperature
  - weaker at high temperature

# Summary

- Dislocations are observed primarily in metals and alloys.
- Strength is increased by making dislocation motion difficult.
- Particular ways to increase strength are to:
  - decrease grain size
  - solid solution strengthening
  - precipitate strengthening
  - cold work
- Heating ([annealing](#)) can reduce dislocation density and increase grain size. This decreases the strength.
